Executive Summary

executive-summary

Stock

stock

This assessment reports the status of the Big Skate (*Beringraja binoculata*) resource in U.S. waters off the coast of ... using data through 2018.

Catches

catches

Information on historical landings of Big Skate are available back to xxxx... (Table [a](#)). Commercial landings were small during the years of World War II, ranging between 329 to 395 metric tons (mt) per year.

(Figures [a-b](#))
(Figure [c](#))

Since 2000, annual total landings of Big Skate have ranged between 135-412 mt, with landings in 2018 totaling 173 mt.

Figure a: Big Skate catch history for the recreational fleets. fig:Exec_catch1

Figure b: Stacked line plot of Big Skate catch history for the commercial fleets. `fig:Exec_catch2`

Table a: Recent Big Skate landings (mt) by fleet.

62 Data and Assessment

data-and-assessment

63 This the first full assessment for Big Skate, which was last assessed as part of the “Other
64 species” Complex. This assessment uses the newest version of Stock Synthesis (3.30.xx).
65 The model begins in 1916, and assumes the stock was at an unfished equilibrium that year.
66 (Figure [d](#)).

Figure d: Map depicting the distribution of California scorpionfish out to 600 ft. The stock assessment is bounded at Pt. Conception in the north to the U.S./Mexico border in the south.
 fig:assess_region_map

67 `##Stock Biomass{-}` (Figure e and Table b).

68 The 2018 estimated spawning biomass relative to unfished equilibrium spawning biomass is
 69 above the target of 40% of unfished spawning biomass at 99.8% (95% asymptotic interval: \pm
 70 99.8%-99.8%) (Figure f). Approximate confidence intervals based on the asymptotic variance
 71 estimates show that the uncertainty in the estimated spawning biomass is high.

Table b: Recent trend in beginning of the year spawning output and depletion for the model for Big Skate.

tab:SpawningDeplete_mod1				
Year	Spawning Output (million eggs)	~ 95% confidence interval	Estimated depletion	~ 95% confidence interval
2010	70693.200	(70693.2- 70693.2)	0.998	(0.998-0.998)
2011	70697.500	(70697.5- 70697.5)	0.998	(0.998-0.998)

2015	0.00	(0-0)	0.00	(0-0)
2016	0.00	(0-0)	0.00	(0-0)
2017	0.00	(0-0)	0.00	(0-0)
2018	0.00	(0-0)	0.00	(0-0)

Figure h: Estimated spawning potential ratio (SPR) for the base-case model. One minus SPR is plotted so that higher exploitation rates occur on the upper portion of the y-axis. The management target is plotted as a red horizontal line and values above this reflect harvests in excess of the overfishing proxy based on the $SPR_{50\%}$ harvest rate. The last year in the time series is 2018. fig:SPR_all

Ecosystem Considerations

ecosystem-considerations

In this assessment, ecosystem considerations were not explicitly included in the analysis. This is primarily due to a lack of relevant data and results of analyses (conducted elsewhere) that could contribute ecosystem-related quantitative information for the assessment.

Reference Points

reference-points

This stock assessment estimates that Big Skate in the model is above the biomass target ($SB_{40\%}$), and well above the minimum stock size threshold ($SB_{25\%}$). The estimated relative depletion level for the base model in 2019 is 99.8% (95% asymptotic interval: $\pm 99.8\%$ -99.8%, corresponding to an unfished spawning biomass of 70709.9 million eggs (95% asymptotic interval: 70709.9-70709.9 million eggs) of spawning biomass in the base model (Table e). Unfished age 1+ biomass was estimated to be 2,814 mt in the base case model. The target spawning biomass ($SB_{40\%}$) is 2,834 million eggs, which corresponds with an equilibrium yield of 5,906 mt. Equilibrium yield at the proxy F_{MSY} harvest rate corresponding to $SPR_{50\%}$ is 5,070 mt (Figure i).

Table e: Summary of reference points and management quantities for the base case model.

Quantity	Estimate	tab:Ref_pts_mod1	
		Low 2.5% limit	High 2.5% limit

1 Introduction

introduction

1.1 Distribution and Life History

distribution-and-life-history

Big Skate (*Raja binoculata*) is the largest of the skate species in North America with a documented maximum length of 244 cm total length and a maximum weight of 91 kg (Eschmeyer and Herald 1983). The species name “binoculata” (two-eyed) refers to the prominent ocellus at the base of each pectoral fin. Big skate range from the Bering Sea to Cedros Island in Baja California, but are uncommon south of Pt. Conception. Big skate have a shallow depth distribution of 3-800 m, but are most common in the 3-110 m depth zone. Big Skate are observed in progressively shallower water in the northern parts of its range. They occur in coastal bays, estuaries, and over the continental shelf, usually on sandy or muddy bottoms, but occasionally on low strands of kelp.

Skates are the largest and most widely distributed group of batoid fish with approximately 245 species ascribed to two families (Ebert and Compagno 2007)(McEachran and Miyake 1990). Skates are benthic fish that are found in all coastal waters but are most common in cold temperatures and polar waters (Ebert and Compagno 2007).

There are eleven species of skates in three genera (Amblyraja, Bathyrāja, and Raja) present in the Northeast Pacific Ocean off California, Oregon and Washington (Ebert 2003). Of that number, just three species (Longnose Skate, *Raja rhina*; Big Skate, *Raja binoculata*; and Sandpaper Skate, *Bathyrāja interrupta*) make up over 95 percent of West Coast Groundfish Bottom Trawl Survey (WCG BTS) catches in terms of biomass and numbers, with the Longnose Skate leading in both categories (with 62 percent of biomass and 56 percent of numbers).

Mating has been observed with distinct pairing with embrace. Big Skate are oviparous and lay horned egg cases up to a foot in length with up to seven embryos per egg case (Eschmeyer and Herald 1983). The female deposits her eggs in pairs on sandy or muddy flats; there is no discrete breeding season and egg-laying occurs year-round (Ebert 2003). Females may use discrete spawning beds, as large numbers of egg cases have been found in certain localized areas (IUCN/SSC Shark Specialist Group 2005). The young emerge after 9 months and measure 18–23 cm (7–9 in).

Female Big Skates mature at 1.3–1.4 m (4 ft 3 in–4 ft 7 in) long and 12–13 years old, while males mature at 0.9–1.1 m (2 ft 11 in–3 ft 7 in) long and seven to eight years old (Bester, C. 2009). The growth rate of Big Skates in the Gulf of Alaska are comparable to those off California, but differ from those off British Columbia. The lifespans of big skates off Alaska are up to 15 years, while those off British Columbia are up to 26 years.

Big Skates are usually seen buried in sediment with only their eyes showing. They feed on polychaete worms, mollusks, crustaceans, and small benthic fishes. Polychaetes and mollusks

comprise a slightly greater percentage of the diet of younger individuals. The eyespots on the skates' wings are believed to serve as decoys to confuse predators. A known predator of big skates is the Broadnose Sevengill Shark (*Notorhynchus cepedianus*). Juvenile Northern Elephant Seals (*Mirownga angustirostris*) are known to consume the egg cases of the Big Skate. Known parasites include the copepod *Lepeophtheirus cuneifer*.

1.2 Early Life History

early-life-history

Bizzarro.

1.3 Map

map

A map showing the scope of the assessment and depicting boundaries for fisheries or data collection strata is provided in Figure 1.

1.4 Ecosystem Considerations

ecosystem-considerations-1

In this assessment, ecosystem considerations were not explicitly included in the analysis. This is primarily due to a lack of relevant data and results of analyses (conducted elsewhere) that could contribute ecosystem-related quantitative information for the assessment.

1.5 Fishery Information

fishery-information

Big Skate are caught in commercial and recreational fisheries on the West Coast using line and trawl gears. There is a limited market for pectoral fins (skate wings).

The history of Big Skate (*Raja binoculata*) is not well documented. They were used as a food source by the native Coastal and Salish Tribes (Batdorf, C 1990) long before Europeans settled in the Pacific Northwest and then as fertilizer by the settlers (???). No directed fishery for Big Skate has been documented; rather, they were taken along with other skates and rays as “scrap fish” and used for fertilizer, fish meal and oil.

Skates have been regarded as a predator on desirable market species such as Dungeness crab, and were thought of as nuisance fish with no appeal as a food item save for small local markets. They had been discarded or harvested at a minimal level until their livers became valued along with those of other cartilaginous fishes for the extraction of vitamin A in the 1940s. Chapman (Chapman, W.M. 1944) recorded that “At present they are being fished

heavily, in common with the other elasmobranchs of the coast, for the vitamins in their livers. The carcasses are either thrown away at sea or made into fish meal. Little use is made of the excellent meat of the wings”.

Little information is available about the historic fishery for Big Skate. In records before 2000, they are lumped together with other skates or in market categories; this necessitates considerable attention to reconstructing the fishery by observing the composition of catches in the modern fishery and applying those to historical records.

1.6 Stock Status and Management History

stock-status-and-management-history

Big Skate were managed in the Other Fish complex until 2015 when they were designated an Ecosystem Component (EC) species. Catches of Big Skate are estimated to have averaged 95 mt from 2007–2011, along with large landings of “Unspecified Skate”. Analysis of Oregon port-sampling data indicates that about 98 percent of the recent Unspecified Skate landings in Oregon were comprised of Big Skate. Such large landings indicates targeting of Big Skate has occurred and an EC designation was not warranted. Based on this evidence, Big Skate was redesignated as an actively-managed species in the fishery. Big skate have been managed with stock-specific harvest specifications since 2017.

The recent OFL of 541 mt was calculated by applying approximate MSY harvest rates to estimates of stock biomass from the Northwest Fisheries Science Center (NWFSC) West Coast Groundfish Bottom Trawl Survey. This survey-based biomass estimate is likely underestimated since Big Skate are distributed all the way to the shoreline and no West Coast trawl surveys have been conducted in water shallower than 55 meters. This introduces an extra source of uncertainty to management and suggests that increased precaution is needed to reduce the risk of overfishing the stock.

There has been consideration for managing Big Skate in a complex with Longnose Skate, the other actively-managed West Coast skate species, but the two species have disparate distributions and fishery interactions (Longnose Skate is much more deeply distributed than Big Skate) and that option was not endorsed. The Pacific Fishery Management Council has chosen to set the Annual Catch Limit (ACL) equal to the Allowable Biological Catch (ABC) with a buffer for management uncertainty (P^*) of 0.45.

1.7 Management Performance

management-performance-1

Table [f](#)

1.8 Fisheries Off Mexico or Canada

fisheries-off-mexico-or-canada

Big Skate and Longnose Skate are landed in the commercial trawl and hook-and-line fisheries in the waters off British Columbia. Assessments of Longnose Skate and Big Skate were conducted by Canada's Division of Fisheries and Oceans in 2015(King, J.R., Surry, A.M., Garcia, S., and P.J. Starr 2015).

For Big Skate, a Bayesian surplus production model failed to provide plausible results, and two data-limited approaches were investigated: Depletion-Corrected Average Catch Analysis (DCAC), and a Catch-MSY (maximum sustainable yield) Approach.

DCAC produced a range of potential yield estimates that were above the long-term average catch, with an upper bound that was three orders of magnitude larger than the long-term average catch. The Catch-MSY approach was found to be quite sensitive to assumptions and was not recommended as the sole basis of advice to managers.

The recommendation for management for the two skate species was that they should be managed with harvest yields based on mean historic catch, with consideration given to survey trends and to the ranges of maximum sustainable yield estimates identified by the Catch-MSY Approach. However, the analysis found no significant trends in abundance indices for Big Skate, and mean historical catches were below the maximum MSY estimate from the catch-MSY results.

#Assessment

##Data Data used in the Big Skate assessment are summarized in Figure 2. Descriptions of the data sources are in the following sections.

###Commercial Fishery Landings

Catch reconstructions for WA, OR, and CA

Oregon Commercial Skate Landings Reconstruction

Oregon Department of Fish and Wildlife (ODFW) provided newly reconstructed commercial landings for all observed skate species for the 2019 assessment cycle (1978 – 2018). In addition, the methods were reviewed at a pre-assessment workshop. Historically, skates were landed as a single skate complex in Oregon. In 2009, longnose skates were separated into their own single-species landing category, and in 2014, big skates were also separated. The reconstruction methodology differed by these three time blocks in which species composition collections diverged (1978 – 2008; 2009 – 2014; 2015 – 2018).

Species compositions of skate complexes from commercial port sampling are available throughout this time period but are generally limited, which precluded the use of all strata for reconstructing landings. Quarter and port were excluded, retaining gear type, PMFC area, and market category for stratifying reconstructed landings within the three time blocks. Bottom trawl gear types include multiple bottom trawl gears, and account for greater than 98% of skate landings . Minor gear types include primarily bottom longline gear, but also include mid-water trawl, hook and line, shrimp trawl, pot gear and scallop dredge.

For bottom trawl gears, trawl logbook areas and adjusted skate catches were matched with strata-specific species compositions. In Time Block 1 (1978 – 2008), all bottom trawl gear types were aggregated due to a lack of specificity in the gear recorded on the fish tickets. However, in Time Blocks 2 and 3, individual bottom trawl gear types were retained. Some borrowing of species compositions was required (31% of strata) and when necessary, borrowed from the closest area or from the most similar gear type . Longline gear landings were reconstructed in a similar fashion as to bottom trawl and required some borrowing among strata as well (25%).

Due to insufficient species compositions, mid-water trawl landings were reconstructed using a novel depth-based approach. Available compositions indicate that the proportion by weight of big skates within a composition drops to zero at approximately 100 fathoms, and an inverse relationship is observed for longnose skate, where the proportion by weight is consistently one beyond 100 – 150 fathoms . Complex-level landings were assigned a depth from logbook entries and these species specific depth associations were used to parse out landings by species. The approach differed somewhat by time block . Landings from shrimp trawls were handled using a similar methodology. Finally, very minor landings from hook and line, pot

gear and scallop dredges were assigned a single aggregated species composition, as they lack any gear-specific composition samples. Landings from within a time block were apportioned by year using the proportion of the annual ticket landings.

Results indicate that the species-specific landings from this reconstruction are very similar to those from Oregon’s commercial catch reconstruction (Karnowski et al. 2014) during the overlapping years but cover a greater time period with methodology more applicable to skates in particular. ODFW intends to incorporate reconstructed skate landings into PacFIN in the future (A. Whitman, ODFW; pers. comm.).

Tribal catch in WA

###Commercial Discards

Commercial discards of Big Skate are highly uncertain. The method used to estimate discards for Longnose Skate was based on a strong correlation between total mortality of that species, and total mortality of Dover Sole for the years 2009–2017 during which Longnose were landed separately from other skates. In contrast, the sorting requirement for Big Skate occurred too recently to provide an adequate range of years for this type of correlation. Furthermore, there is greater uncertainty in the total mortality for the shallow-water species with which Big Skate most often co-occurs, such as Sand Sole and Starry Flounder, than there is for Dover Sole, which has been the subject of recurring stock assessments.

However, those involved in the fishery for both skate species report that discarding for Big Skate and Longnose Skate in the years prior to 1995 were driven by the same market forces and the discard rates were similar. primarily lack of markets or fish processors accepting only skate wings that had been separated at-sea, as well as the quantitative have more uncertainty in their own catch estimates have no stock assessment and more uncertain mortality estimated total mortality and Dover Sole for which a correlation between relationship (???), ###Commercial Fishery Length and Age Data

The input sample sizes were calculated via the Stewart Method (Ian Stewart, personal communication, IPHC):

$$\text{Input effN} = N_{\text{trips}} + 0.138 * N_{\text{fish}} \text{ if } N_{\text{fish}}/N_{\text{trips}} \text{ is } < 44$$

$$\text{Input effN} = 7.06 * N_{\text{trips}} \text{ if } N_{\text{fish}}/N_{\text{trips}} \text{ is } \geq 44$$

Data Source 3

###Fishery-Independent Data Sources

Alaska Fisheries Science Center (AFSC) Triennial Shelf Survey

Research surveys have been used since the 1970s to provide fishery-independent information about the abundance, distribution, and biological characteristics of Big Skate. A coast-wide survey was conducted in 1977 (Gunderson, Donald Raymond and Sample, Terrance M. 1980) by the Alaska Fisheries Science Center, and repeated every three years through 2001. The final year of this survey, 2004, was conducted by the NWFSC according to the AFSC protocol. We refer to this as the **Triennial Survey**.

The survey design used equally-spaced transects from which searches for tows in a specific depth range were initiated. The depth range and latitudinal range was not consistent across years, but all years in the period 1980-2004 included the area from 40° 10'N north to the Canadian border and a depth range that included 55-366 meters, which spans the range where the vast majority of Big Skate encountered in all trawl surveys. Therefore the index was based on this depth range. The survey as conducted in 1977 had incomplete coverage and is not believe to be comparable to the later years, and is not used in the index.

An index of abundance was estimated based on the VAST delta-GLMM model as described for the NWFSC Combo Index above. In this case as well, Q-Q plots indicated slightly better performance of the gamma over lognormal models for positive tows (Figure ??).

Northwest Fisheries Science Center West Coast Groundfish Bottom Trawl Survey

In 2003, the NWFSC took over an ongoing slope survey the AFSC had been conducting, and expanded it spatially to include the continental shelf. This survey, referred to in this document as the **NWFSC Combo Survey**, has been conducted annually since. It uses a random-grid design covering the coastal waters from a depth of 55 m to 1,280 m from late-May to early-October (Bradburn, M.J. and Keller, A.A and Horness, B.H. 2011 , Keller, A.A. and Wallace, J.R. and Methot, R.D. 2017). Four chartered industry vessels are used each year (with the exception of 2013 when the U.S. federal-government shutdown curtailed the survey). Yellowtail catches in the NWFSC Combo Survey are shown in ??.

The data from the NWFSC Combo survey was analyzed using a spatio-temporal delta-model (Thorson, J. T. and Shelton, A. O. and Ward, E. J. and Skaug, H. J. 2015), implemented as an R package VAST (Thorson, James T. and Barnett, Lewis A. K. 2017) and publicly

319 available online (<https://github.com/James-Thorson/VAST>). Spatial and spatio-temporal
320 variation is specifically included in both encounter probability and positive catch rates, a
321 logit-link for encounter probability, and a log-link for positive catch rates. Vessel-year effects
322 were included for each unique combination of vessel and year in the database.

324 *Data Source 1 Length Composition*

325 **Triennial Survey** *Data Source 2 Index Standardization* VAST

###Biological Parameters and Data

Measurement Details and Conversion Factors

Disc width to total length (estimated by Ian on Apr 15, similar to Ebert 2008 estimates for Alaska) $L = 1.3399 * W$ estimated from 95 samples from WCGBTS where both measurements collected (R-squared = 0.9983). Little sex difference observed, so using single relationship for both sexes. Inter-spiracle width to total length from Downs & Cheng (2013): $L = 12.111 + 9.761ISW$ (*females*) $L = 3.824 + 10.927ISW$ (*males*)

Love et al. (1987)

Length and Age Compositions

Length comps (some based on widths)

WCGBTS Lengths from all years except 2006 and 2007 Widths in 2006 and 2007

Triennial Survey Sample sizes: 3 in 1998 (all widths), 84 in 2001 (3 widths, 81 lengths), 100 in 2004 (all lengths) Triennial survey About 90+ samples in each of 2001 and 2004 Only 3 unsexed fish from 1998

Commercial fisheries In process Discard comps from 2010-2015

Length compositions were provided from the following sources:

- Source 1 (*type, e.g., commercial dead fish, research, recreational, yyyy-yyyy*)
- Source 2 (*type, yyyy-yyyy*)
- Source 3 (*research, yyyy, yyyy, yyyy, yyyy*)

The length composition of all fisheries aggregated across time by fleet is in Figure 3. Descriptions and details of the length composition data are in the above section for each fleet or survey.

Age Structures

von Bertalanffy growth curve (von Bertalanffy, L 1938), $L_i = L_{\infty}e^{(-k[t-t_0])}$, where L_i is the length (cm) at age i , t is age in years, k is rate of increase in growth, t_0 is the intercept, and L_{∞} is the asymptotic length.

Ages WCGBTS Currently only 333 ages from 2010 present in data warehouse as of Apr 15 Patrick submitting an 300 additional ages from 2016 and 2017 to Beth on Apr 2 and promised further additions during the week of Apr 15.

Triennial Survey No ages

356 Commercial fisheries 2009 samples from WA were stratified by length, so should be treated
357 as conditionals

358 **Aging Precision and Bias**

359 **Weight-Length**

360 Estimated by Ian based on WCGBT samples (n = 1159) $Weight = 0.0000074924 * Length^{2.9925}$ (Figure 4).

362 **Sex Ratio, Maturity, and Fecundity**

363 The female maturity relationship was based on visual maturity estimates from port sam-
364 plers (n = 278, of which 241 were from Oregon and 37 from Washington, with 24 mature
365 specimens) as well as 55 samples from the WCGBTs (of which 4 were mature). The result-
366 ing relationship was $L_{50\%} = 148.2453$ with a slope parameter of $Beta = -0.13155$ in the
367 relationship $M = (1 + Beta(L - L_{50\%}))^{-1}$ (Figure 5).

368 **Natural Mortality**

369 The Hamel prior for M is $\text{lognormal}(\ln(5.4/\text{max age}), .438)$, which based on 1 age-15 fish out
370 of 1034 observed in the WCGBTs results in $\text{lognormal}(-1.021651, 0.438)$

371 If it needs to be fixed, it should be set to $M = 5.4/\text{max age} = 5.4/15 = 0.36$

372 ~~###~~Environmental or Ecosystem Data Included in the Assessment In this assessment,
373 neither environmental nor ecosystem considerations were explicitly included in the analysis.
374 This is primarily due to a lack of relevant data and results of analyses (conducted elsewhere)
375 that could contribute ecosystem-related quantitative information for the assessment.

376 ##Previous Assessments

377 ###History of Modeling Approaches Used for this Stock

378 Deriving estimates of OFL for species in the “Other Fish” complex or potential alternative
379 complexes

380 The current “Other Fish” complex and proposed alternatives include a number of species for
381 which estimates of OFL contributions are not available from stock assessments or data-poor
382 methods. Four of the species had OFL contributions for the 2013–2014 management cycle
383 calculated by applying approximate MSY harvest rates to estimates of stock biomass from
384 the NWFSC West Coast Bottom Trawl Survey (Bradburn et al., 2012). This approach is
385 described in detail in Cope et al. (2012).

396 ##Model Description

397 ###Transition to the Current Stock Assessment

398 ###Summary of Data for Fleets and Areas There are xxx fleets in the base model. They
399 include:

400 *Commercial:* The commercial fleets include ...

401 *Recreational:* The recreational fleets include ...

402 *Research:* There are xx sources of fishery-independent data available ...

403 ###Other Specifications

404 `###Modeling Software` The STAT team used Stock Synthesis 3 version 3.30.05.03 by
405 Dr. Richard Methot at the NWFSC. This most recent version was used, since it included
406 improvements and corrections to older versions. The r4SS package (GitHub release number
407 v1.27.0) was used to post-processing output data from Stock Synthesis.

408 `###Data Weighting`

409 `###Priors` The log-normal prior for female natural mortality were based on a meta-analysis
410 completed by Hamel (2015), as described under “Natural Mortality.” Female natural mor-
411 tality was fixed at the median of the prior, 0.xxx for an assumed maximum age of xx. An
412 uninformative prior was used for the male offset natural mortality, which was estimated.

413 The prior for steepness (h) assumes a beta distribution with parameters based on an update
414 for the Thorson-Dorn rockfish prior (Dorn, M. and Thorson, J., pers. comm.), which was
415 endorsed by the Science and Statistical Committee in 2018. The prior is a beta distribution
416 with $\mu=0.xxx$ and $\sigma=0.xxx$. Steepness is fixed in the base model at the mean of the
417 prior. The priors were applied in sensitivity analyses where these parameters were estimated.

418 `###Estimated and Fixed Parameters` A full list of all estimated and fixed parameters is
419 provided in Tables ??.

420 The base model has a total of xxx estimated parameters in the following categories:

- 421 • xxx,
- 422 • xxx
- 423 • xxx, and
- 424 • xxx selectivity parameters

425 The estimated parameters are described in greater detail below and a full list of all estimated
426 and parameters is provided in Table ??.

427 *Growth.*

428 *Natural Mortality.*

429 *Selectivity.*

430 *Other Estimated Parameters.*

431 *Other Fixed Parameters.*

456 ##Base Case Model Results The following description of the model results reflects a base
457 model that incorporates all of the changes made during the STAR panel (see previous sec-
458 tion). The base model parameter estimates and their approximate asymptotic standard
459 errors are shown in Table ?? and the likelihood components are in Table ?. Estimates of
460 derived reference points and approximate 95% asymptotic confidence intervals are shown in
461 Table e. Time-series of estimated stock size over time are shown in Table ??.

462 ###Parameter Estimates

463 The additional survey variability (process error added directly to each year's input variabil-
464 ity) for all surveys was estimated within the model.

465 (Figure 7).

466 The stock-recruit curve ... Figure 8 with estimated recruitments also shown.

467 ###Fits to the Data Model fits to the indices of abundance, fishery length composition,
468 survey length composition, and conditional age-at-length observations are all discussed be-
469 low.

470 ###Uncertainty and Sensitivity Analyses A number of sensitivity analyses were conducted,
471 including:

472 1. Sensitivity 1

473 2. Sensitivity 2

474 3. Sensitivity 3

475 4. Sensitivity 4

476 5. Sensitivity 5, etc/

477 ###Retrospective Analysis

478 ###Likelihood Profiles

479 ###Reference Points Reference points were calculated using the estimated selectivities and
480 catch distribution among fleets in the most recent year of the model, (2017). Sustainable
481 total yield (landings plus discards) were 5,070 mt when using an $SPR_{50\%}$ reference harvest
482 rate and with a 95% confidence interval of 5,070 mt based on estimates of uncertainty. The
483 spawning biomass equivalent to 40% of the unfished level ($SB_{40\%}$) was 2,834 mt.

484 (Figure 12

485 The 2018 spawning biomass relative to unfished equilibrium spawning biomass is
486 above/below the target of 40% of unfished levels (Figure 13). The relative fishing intensity,
487 $(1 - SPR)/(1 - SPR_{50\%})$, has been xxx the management target for the entire time series
488 of the model.

489 Table e shows the full suite of estimated reference points for the base model and Figure 14
490 shows the equilibrium curve based on a steepness value xxx.

491 #Harvest Projections and Decision Tables The forecasts of stock abundance and yield were
492 developed using the final base model, with the forecasted projections of the OFL presented
493 in Table [g](#).

494 The forecasted projections of the OFL for each model are presented in Table [h](#).

495 #Regional Management Considerations

496 #Research Needs There are a number of areas of research that could improve the stock
497 assessment for Big Skate. Below are issues identified by the STAT team and the STAR
498 panel:
